

NuggBudz

Split a 20-piece box with the stranger
next to you

Hackathon pitch · live at nuggbudz.com ·

2AM Logic

Concept render – generated imagery, not a photograph of a
real restaurant or product.

A concept render featuring a golden, multi-faceted object, possibly a gem or a stylized rock, resting on a black and white checkered floor. The background is a dark, empty parking lot at night, illuminated by a street light. A large, semi-transparent rectangular plane with a purple-to-blue gradient is positioned behind the golden object. The text "The spread is real" is overlaid in a bold, white font with a pink outline.

The spread is real

Concept render – generated imagery, not a photograph of a real restaurant or product.

Buying for one is the expensive way to buy

A 20-piece box is **\$7.99**. A 10-piece is **\$6.99** — 87% of the price for half the food.

- Two people in the same queue pay \$13.98 for what \$7.99 buys
- Neither of them has any way to find the other
- The tax lands on whoever is eating alone

The inversion is the whole category, not a promo

\$0.40 a nugget in the 20pc against \$0.70 solo — a 1.75× premium for buying small.

Why now

- **Chains moved value into bulk bundles** — the cheap unit price is only on the box one person will not finish
- **Stateful edge compute went per-object cheap** — a whole metro's live matching now fits in one addressable actor with no idle cost
- **Phones carry location and payment** — a pairing can settle before the food is cold

Finding the second buyer

Concept render – generated imagery, not a photograph of a real restaurant or product.

The protocol

1. Sign in, pick a deal — **no location prompt**, ever
2. The server places you in a pool **shard** — sized so your whole matching radius sits inside it
3. Another buyer within **2 miles** wants the same box → both phones are paired live
4. Longest waiter orders, the other walks over; both see the same settlement and a pickup code

Concept render — generated imagery, not a photograph of a real place or person.

Everyone else assumes you already know the other person

Alternative	What it does	Why it does not solve this
McDonald's, Wendy's, Burger King apps	Sell the cheap bulk box	Assume one buyer eats twenty nuggets
DoorDash / Uber Eats group orders	Share a cart via a link	You must already have the other person
Splitting with a friend	Works perfectly	Requires a friend, here, hungry now

Cross-merchant, cross-cell liquidity — no chain app pools it.

Concept render — generated imagery, not a photograph of a real product.

Who pays what, to the cent

Line	Amount
Two solo 10pc boxes	\$13.98
One 20pc box	\$7.99
Pairing fee	\$0.99
Each buyer pays	\$4.49
Each buyer saves	\$2.50 (36%)

Platform keeps \$0.99 — 11% of the \$8.98 collected. Integer cents; shares sum back exactly.

The spread is in every deal in the catalogue

Merchant	Box	Solo	Each pays	Each saves	Spread
McDonald's	\$7.99	\$6.99	\$4.49	\$2.50	\$5.99
Wendy's	\$8.49	\$7.29	\$4.74	\$2.55	\$6.09
Burger King	\$5.99	\$4.49	\$3.49	\$1.00	\$2.99

Gross retail spread per pairing — \$5.99 is 43% of the \$13.98 two solo buyers would spend.

One Durable Object per shard — a 2-mile radius decides who pairs

The **radius** is the market, not the shard. One event at a time: no double-pairing.

Deployed, and verified end to end

- `nuggbudz.com` — real two-phone pairing over WebSockets
- **Every** end-to-end check passes across Worker, Durable Object, KV and D1
- Settlement, geo, matchmaking and the wire protocol are pure logic, tested without a runtime
- **Not yet proven**: no users, no revenue, no pilot — that is what the ask is for
- Shipped in the hackathon window by an agent pipeline — every feature a reviewed, CI-green pull request by `rjwalters` and `turian`

Live demo — two phones, one cell

Plan	What happens
A	Judges open the URL on their own phones and pair with us
B	Our two phones on a hotspot — same flow, same cell
C	No usable edge geo → the server places us in the fixed demo cell and says so on screen
D	No network at all → the recorded end-to-end runs in <code>refs/smoke-runs.md</code>

The model is arithmetic on the fee

Pairings in one cell	Platform	Buyer savings unlocked
10	\$9.90	\$50.00
25	\$24.75	\$125.00
100	\$99.00	\$500.00

Gross of processing, support and fraud. \$5.00 saved per pairing: the spread splits 83% buyer / 17% platform.

Judges: open it on your phone and pair with us

Then one pilot cell — one store cluster, 30 days — to measure the number we cannot derive: how long a buyer will wait for a buddy.

Concept render — generated imagery, not a photograph of a real place or person.

Appendix — every figure here is derived, not typed

- `shared/deals.ts` + `shared/economics.ts` are the only sources of money in this deck
- `scripts/deck-ledger.ts` derives each figure; `test/deck.test.ts` fails if a slide disagrees
- Reprice a deal and `pnpm test` goes red until the slides are corrected
- Chart data is generated from the catalogue, so the figure cannot outlive a price change
- Every generated image carries its prompt, model and hash in `assets/_prompts.json`
